## Lecture 28: Antithetic variables

Ciaran Evans

# Warmup: antithetic sampling

Work with your neighbor on the questions on the handout / course website:

```
https://sta379-s25.github.io/practice_questions/pq_28_warmup.html
```

Then we will discuss as a class

- Use Monte Carlo integration to approximate another integral
- Explore variability of two different estimators

```
Warmup: antithetic sampling
theta_hat_as <- rep(NA, nsim)
for(i in 1:nsim){
  u \leftarrow runif(n/2)
  theta hat as[i] \leftarrow sum(g(u) + g(1-u))/n
(var(theta hat mc) - var(theta hat as))/var(theta hat mc)
## [1] 0.9649457
u <- runif(10000)
cor(g(u), g(1-u))
```

## [1] -0.9678501

### Antithetic variables

$$\theta = \mathbb{E}[g(U)]$$
  $U \sim \textit{Uniform}(0,1)$ 

#### **Antithetic sampling:**

- ▶ **Theorem:** If g is monotone, then  $Cor(g(U), g(1-U)) \le 0$
- ► Sample  $U_1, ..., U_{n/2} \stackrel{iid}{\sim} Uniform(0,1)$
- $\widehat{\theta}_{AS} = \frac{1}{n} \sum_{i=1}^{n/2} (g(U_i) + g(1 U_i))$
- Var( $\widehat{\theta}_{AS}$ ) =  $\frac{(1+\rho)Var(g(U))}{n}$  where  $\rho = Cor(g(U), g(1-U))$

## Another example

Suppose we want to approximate the integral

$$\theta = \int_{1}^{\infty} e^{-x} \frac{4}{x^5} dx = \mathbb{E}[e^{-X}]$$

where X has pdf  $f(x) = \frac{4}{x^5}$ , x > 1.

#### Simple Monte Carlo:

- $\triangleright$   $X_1,...,X_n \stackrel{iid}{\sim} f$
- $\widehat{\theta}_{MC} = \frac{1}{n} \sum_{i=1}^{n} e^{-X_i}$

**Question:** How do we sample  $X_i \sim f$ ?

# Another example

Suppose we want to approximate the integral

$$\theta = \int_{1}^{\infty} e^{-x} \frac{4}{x^5} dx = \mathbb{E}[e^{-X}]$$

where *X* has pdf  $f(x) = \frac{4}{x^5}$ , x > 1.

### Simple Monte Carlo:

- $V_1,...,U_n \stackrel{iid}{\sim} Uniform(0,1)$
- $X_i = F^{-1}(U_i)$
- $\widehat{\theta}_{MC} = \frac{1}{n} \sum_{i=1}^{n} e^{-X_i} = \frac{1}{n} \sum_{i=1}^{n} e^{-F^{-1}(U_i)}$

**Question:** Can we use antithetic sampling here?

# Another example

Suppose we want to approximate the integral

$$\theta = \int_{1}^{\infty} e^{-x} \frac{4}{x^5} dx = \mathbb{E}[e^{-X}]$$

where X has pdf  $f(x) = \frac{4}{x^5}$ , x > 1.

# Antithetic sampling with inverse transform

Suppose we want to approximate

$$\theta = \mathbb{E}[g(X)]$$
  $X \sim f$ 

If we can generate X with the inverse transform method, then

$$\theta = \mathbb{E}[g(F^{-1}(U))]$$
  $U \sim \textit{Uniform}(0,1)$ 

#### **Antithetic sampling:**

- ► **Theorem:** If g is monotone, then  $Cor(g(F^{-1}(U)), g(F^{-1}(1-U))) \le 0$
- ► Sample  $U_1, ..., U_{n/2} \stackrel{iid}{\sim} Uniform(0,1)$

$$\widehat{\theta}_{AS} = \frac{1}{n} \sum_{i=1}^{n/2} (g(F^{-1}(U_i)) + g(F^{-1}(1-U_i)))$$

#### Your turn

Try antithetic sampling with the inverse transform method:

 $https://sta379\text{-}s25.github.io/practice\_questions/pq\_28.html\\$ 

- Start in class
- Welcome to work with a neighbor
- Solutions are posted on the course website
